

Fundamentals of Switch-Mode Power Supply Testing

Practical Tips & Techniques

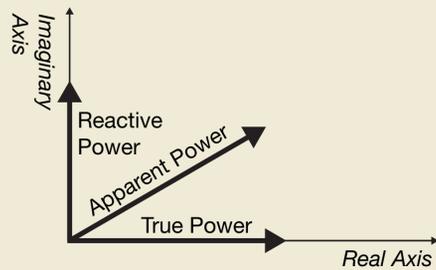

Power supplies are driving to a level of efficiency never seen before, requiring design engineers to perform numerous specialized power measurements that are time-consuming and complex. With the right oscilloscope and the tips outlined in this poster, learn how to better ensure the reliability, stability, compliance, and safety of your switch-mode power supply (SMPS) design.

Power Quality

Power Quality Issues

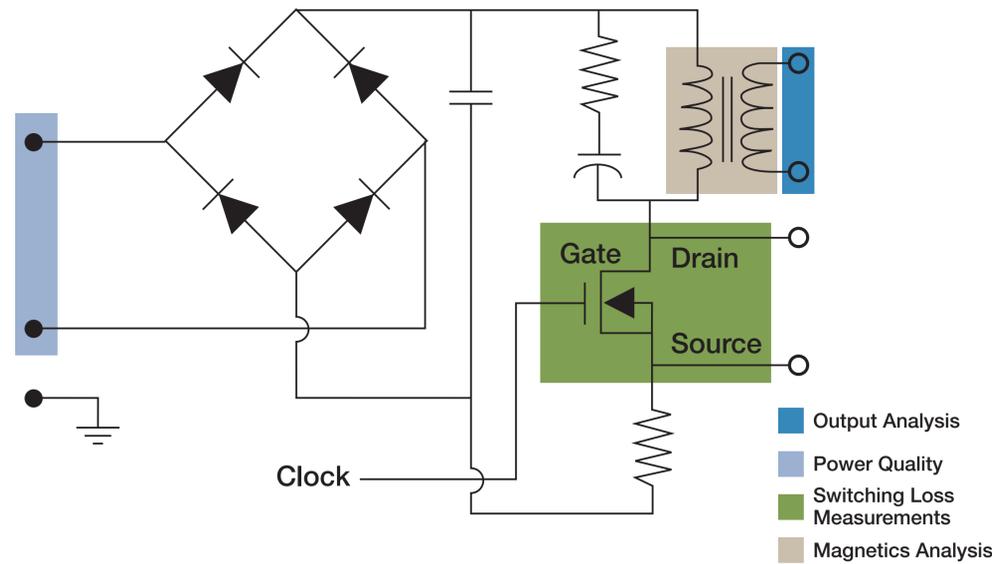

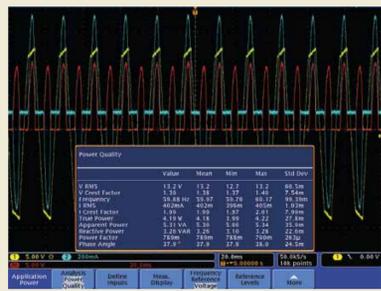

- To determine the effect of the insertion of a power supply, voltage and current parameters must be measured directly on the input power line.
- Power quality measurements include:
 - True, Apparent or Reactive Power
 - Power Factor/Crest Factor
 - Pre-compliance Testing to EN61000-3-2 Standards
 - Total Harmonic Distortion (THD)

■ Apparent Power = $I_{rms} * V_{rms}$

■ Power Factor = $\frac{\text{True Power}}{\text{Apparent Power}}$

■ Crest Factor = $\frac{V_{peak}}{V_{rms}}$

Probing Considerations

Probes and probing techniques affect the quality of a measurement. Loading and skew between probes can introduce error and distortion in power measurements.

Tip: Eliminate skew between current and voltage probes. Since power is the product of voltage and current accurate measurements are made with time-aligned voltage and current waveforms. Tektronix oscilloscopes with the TekVPI interface simplify measurement setup with automated deskew.

Tip: Remove voltage offset by using the built-in DC offset adjustment controls on differential probe. Additionally run the oscilloscope self-calibration routine as often as necessary to ensure accurate voltage measurements.

Tip: A TekVPI current probe has a Degauss/AutoZero button on the probe body. Depressing the AutoZero button will remove any DC offset error present in the measurement system as a result of any residual magnetic field.

Tektronix Oscilloscopes

- 100 MHz to 3.5 GHz models
- Up to 4 analog and 16 digital channels
- Comprehensive Probing Solutions
 - TekVPI™ interface for easy probe connectivity
 - AC/DC current probes
 - Differential probes to make floating measurements
 - High voltage with high bandwidth for accurate characterization of fast edges
- Integrated Power Analysis Software
 - Automated power measurements including switching loss, ripple, power quality, current harmonics and modulation analysis
 - Measure core loss and BH curves on magnetic components
 - Quickly deskew voltage/current probes with built-in automation
 - Generate customized reports

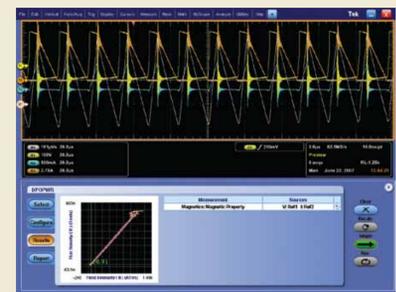

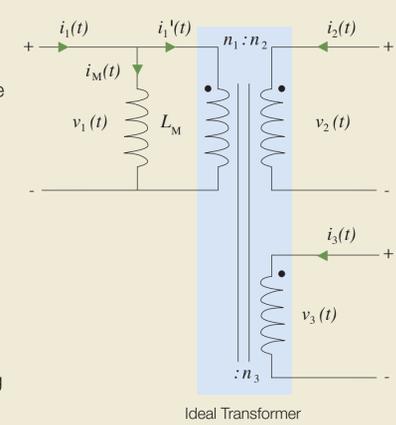

Magnetics Analysis

- Inductors
 - Used in power supplies as a filter or energy storage device

$$L = \frac{\int -Vdt}{I}$$

Where:

- L is the inductance (Henry).
- V is the voltage across the inductor.
- I is the current through the inductor.
- dt is the rate of change in a signal; the slew rate.
- Transformers
 - Multiple-winding inductor or transformer used for stepping voltages up or down with the same net power level
 - Two types of power losses are associated with magnetic elements:
 - Core Loss: Composed of hysteresis loss and eddy current loss. The hysteresis loss is a function of the frequency of operation and the AC flux swing.
 - Copper Loss: Due to the resistance of the copper winding wire.

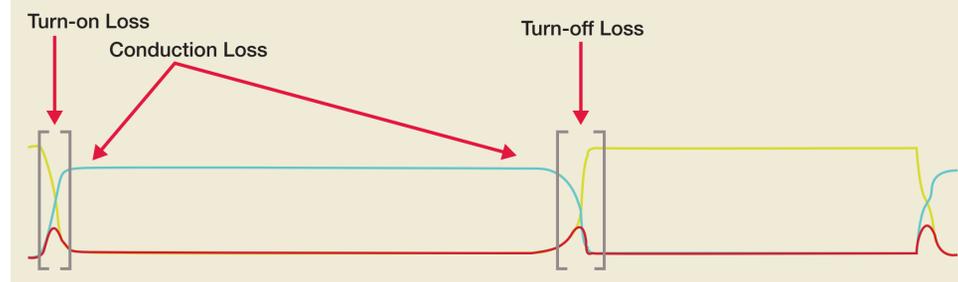

Switching Loss Measurements

- Switched-Mode Device
 - Compared to resistors and linear-mode devices, transistors dissipate very little power in either the On or Off states, achieving high efficiency with low heat dissipation.
 - Transistor switch circuits often dissipate the most energy during transitions because circuit parasitics prevent the devices from switching instantaneously.
 - For the most part, the switching device determines the overall performance of an SMPS.

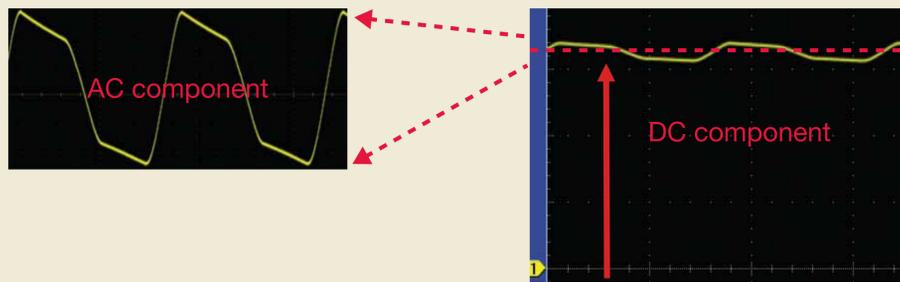

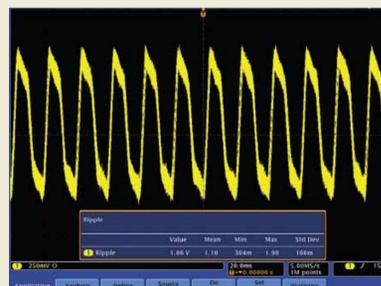

Power Loss Overview

- Turn-on Loss
 - Energy losses when the switching device changes from its non-conducting state to its conducting state
- Conduction Loss
 - Losses in the switching device when it is in saturation
- Turn-off Loss
 - Energy losses when the switching device changes from its conducting state to its non-conducting state.

Output Analysis

- Ripple is the periodic AC component
 - On top of the DC voltage output
- Ripple frequency is related to
 - Line frequency
 - ~120 Hz in countries with 60 Hz power
 - ~100 Hz in countries with 50 Hz power
 - Switching frequency
 - Typically > 100 kHz
